Method and Apparatus for Depositing Antireflective Coating**CROSS REFERENCE TO RELATED APPLICATION**

10 *gub*
C1 This is a continuation-in-part patent application of Application Serial
No.08/567,338, filed December 5, 1995, entitled "Anti-Reflective Coating and Method for
Depositing Same."

BACKGROUND OF THE INVENTION

15

The present invention relates to apparatus for, and the processing of,
semiconductor wafers. In particular, the invention relates to the deposition of antireflective
layers during wafer processing.

20

In the manufacture of integrated circuits, photolithographic techniques are
used to define patterns for layers in an integrated circuit. Typically, such photolithographic
techniques employ photoresist or other light-sensitive material. In conventional processing,
the photoresist is first deposited on a wafer, and then a mask having transparent and opaque
regions which embody the desired pattern, is positioned over the photoresist. When the
mask is exposed to light, the transparent portions allow light to expose the photoresist in
those regions, but not in the regions where the mask is opaque. The light causes a chemical
reaction to occur in the exposed portions of photoresist. A suitable chemical, or a chemical
vapor or ion bombardment process, then is used to selectively attack either the reacted or
unreacted portions of the photoresist. With the photoresist pattern remaining on the wafer
itself now acting as a mask for further processing, the integrated circuit can be subjected to
additional process steps. For example, material may be deposited on the circuit, the circuit
may be etched, or other known processes carried out.

30

In the processing of integrated circuit devices with small feature sizes, for
example, feature sizes having critical dimensions less than one-half micron, sophisticated
techniques involving equipment known as steppers, are used to mask and expose the
photoresist. The steppers for such small geometry products generally use monochromatic
